TQ Solution

for TTOpt solver

Problem Statement

... task is to take TTOpt solver (use this <u>example</u>) and create simple software that the user can install locally to find minima of multi-dimensional function in Python and a simple web page that can do the same. The most important aspect is that the code for TTopt must be hidden from the user, while the simple software is straightforward to use.

- Source Code: Python or C++ implementation of the algorithm.
- Dockerfile: For containerized application.
- **SDK Module**: Enable easy integration of the algorithm.
- **Qt**: Example of the solution for several functions.
- o **CI/CD pipeline**: Perform build, deploy and unit tests of your solution.
- Docker and Github.
- Detailed installation instructions: Prepare the instructions for scientists not familiar with software development.

- Requirements
 - Functional requirements
 - local installation stand alone SW
 - utilize TTOpt solver locally
 - software must display the optimization results to the user: minima with func vector + logs
 - simple UI
 - Web-based version
 - utilize TTOpt solver on the server in cloud
 - similar simple UI.
 - must display optimization results
 - downloadable solution result with logs

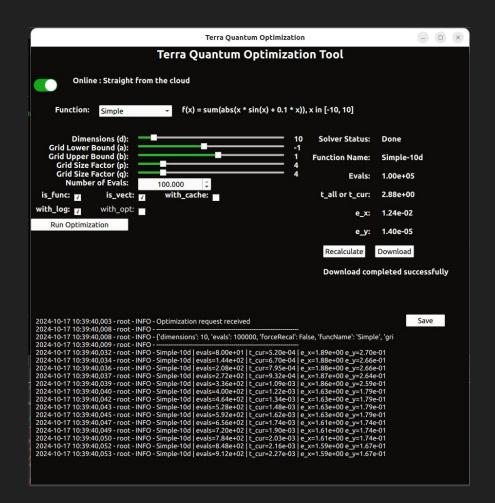

Requirements

- Non functional requirements
 - Performance complete optimization within a reasonable time frame (e.g., ~ under a minute), responsive web UI
 - Usability simple UI, accessible and easy to use on different devices and browsers
 - Security TTOpt solver code must be isolated
 - Compatibility local software must run on major operating systems (Windows, macOS, Linux)
 - Reliability handle errors, provide clear msgs, uptime 99.9%
 - Scalability handle multiple concurrent users
 - Maintainability well-documented future updates
 - o **Installation** one-click installer for local sw

Solution

Standalone, local SW

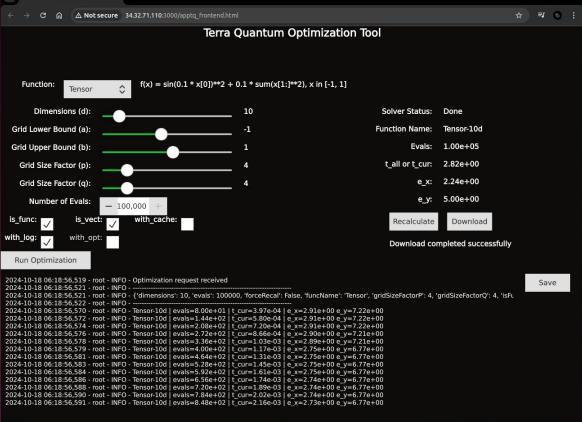

Solution

Web based

SW

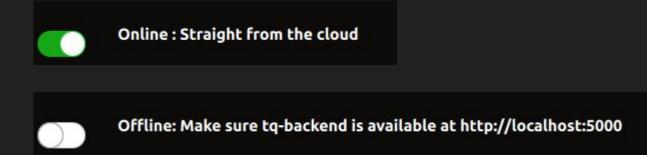

apptq frontend

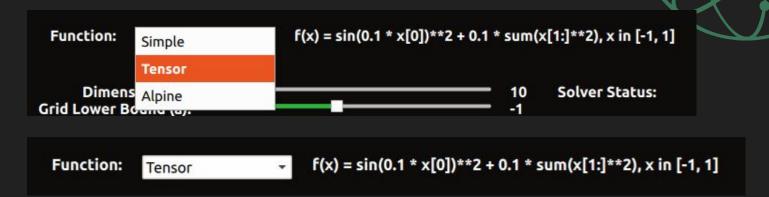

- Features
 - Modes: Online & Offline
 - Desktop version can use TTSolver available on cloud as well as local installation

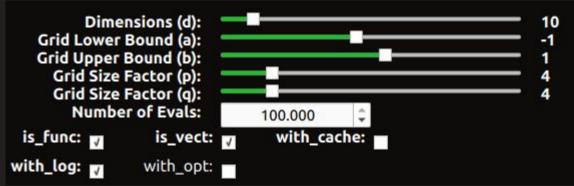

- Features
 - Easy drop down for <u>function selection</u>

- Features
 - Simple & smooth sliders to adjust input parameters

Features

- Results → with status
 - Processing
 - o Done
 - Error : error msg
- Easy parsing of output

INFO - Optimization completed successfully
INFO - -------calculated info-----INFO - Tensor-10d | evals=1.00e+05 | t_all=2.93e+00 | e_x=2.24e+00 e_y=5.00e+00

	Solver Status:	Done
	Function Name:	Tensor-10d
>	Evals:	1.00e+05
	t_all or t_cur:	2.93e+00
	e_x:	2.24e+00
	e_y:	5.00e+00
	Recalculate	Download

Features

- To improve performance, TTSolver saves the previous calculations done by you and fetches the results faster when requested again. But you never know! You may want to <u>recalculate</u> the minima!
- <u>Download</u> button to get complete info logs from TTSolver
- Of course with download status msg

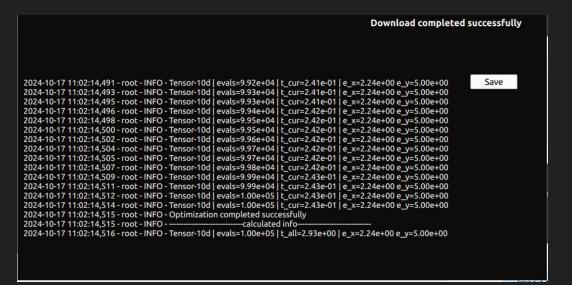

Features

 See the logs directly in Text panel (can do live stream but not in PoC. You have to press download button to see logs). And finally the <u>Save</u> button to save the logs in .txt file format.

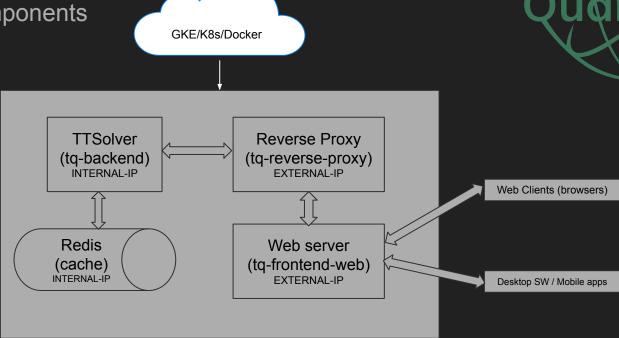

Architecture

Key components

Supporting components

SDK (tq-sdk)

(Web Browser or

Standalone App)

Architecture

Sequence flow

(External IP)

(External IP)

(Internal IP)

(Internal IP)

Architecture

- Components
 - Backend (tq-backend)
 - Internal component with only an Internal IP
 - Performs the actual calculations for finding minima
 - Communicates with Redis Cache for data storage and retrieval
 - Not directly accessible from outside the cluster
 - Redis Cache
 - Internal component with only an Internal IP
 - Provides fast, in-memory data storage for the TTSolver Backend
 - Not directly accessible from outside the cluster

Architecture

- Components
 - Frontend Web UI
 - Exposed with an External IP
 - Serves the user interface for calculation requests
 - Communicates with the Reverse Proxy to forward requests to the backend
 - Reverse Proxy
 - Exposed with an External IP
 - Acts as an intermediary between the Frontend and Backend
 - Handles known endpoints only (e.g., public frontend)
 - Provides an additional layer of security

Disclaimer

- Google Cloud: One can use any cloud service provider to host the solution. I choose Google cloud service because I already exhausted AWS & Azure's free period / initial free credits. And this is my first time with GCR + GKE. Good that I get to explore!
- Redis: Redis cache is not included in the solution. It doesn't allow
 to deploy services using Redis with its open source version. Sad
 but fair enough. I instead use unordered_map directory directly
 inside backend service app. Plus GCR takes care of scaling in case
 of heavy memory requests.
- **Github commits:** Some commit messages on solution repo may show little frustration! But I'm sure it will bring some chuckles:)
- Code visibility: I have kept the code open / public, anyone can see the solution. If you have concerns, feel free to write me: pratik.prajapati1989@gmail.com

... thank you!
